The Lena River delta: An accumulative environment

Sediment transfer: “a jerky conveyor belt” [Walling, 1983]

- How we define ‘sediment concentration’?
- How (when, where) we measure sediment concentrations and fluxes?
- How the data are treated?
- How the data are published, stored and retrieved?
- How the data are used in flux calculations?

Suspended sediment data

- Virtually unavailable
- Mostly historical
- Scarce
- Inaccurate
- GS Kyusyur: 17 years, 71 obs.

Suspended sediment data: Lena at Tabaga, 1966

Suspended sediment data: Lena at Tabaga, 1964

Sediment Rating Curve

1. *A concept*

A belief that one variable has the capacity to describe the totality of processes affecting the sediment transport:

$$\text{SSC}, Y_s \sim Q, Y_Q$$

Based on $Q, Y_Q \sim i$ and $Y_s \sim i$, where i – runoff formation intensity, and stream power equation.

2. *A model*

A physically-based distributed model of sediment detachment, routing, storage and deposition is yet to be developed.

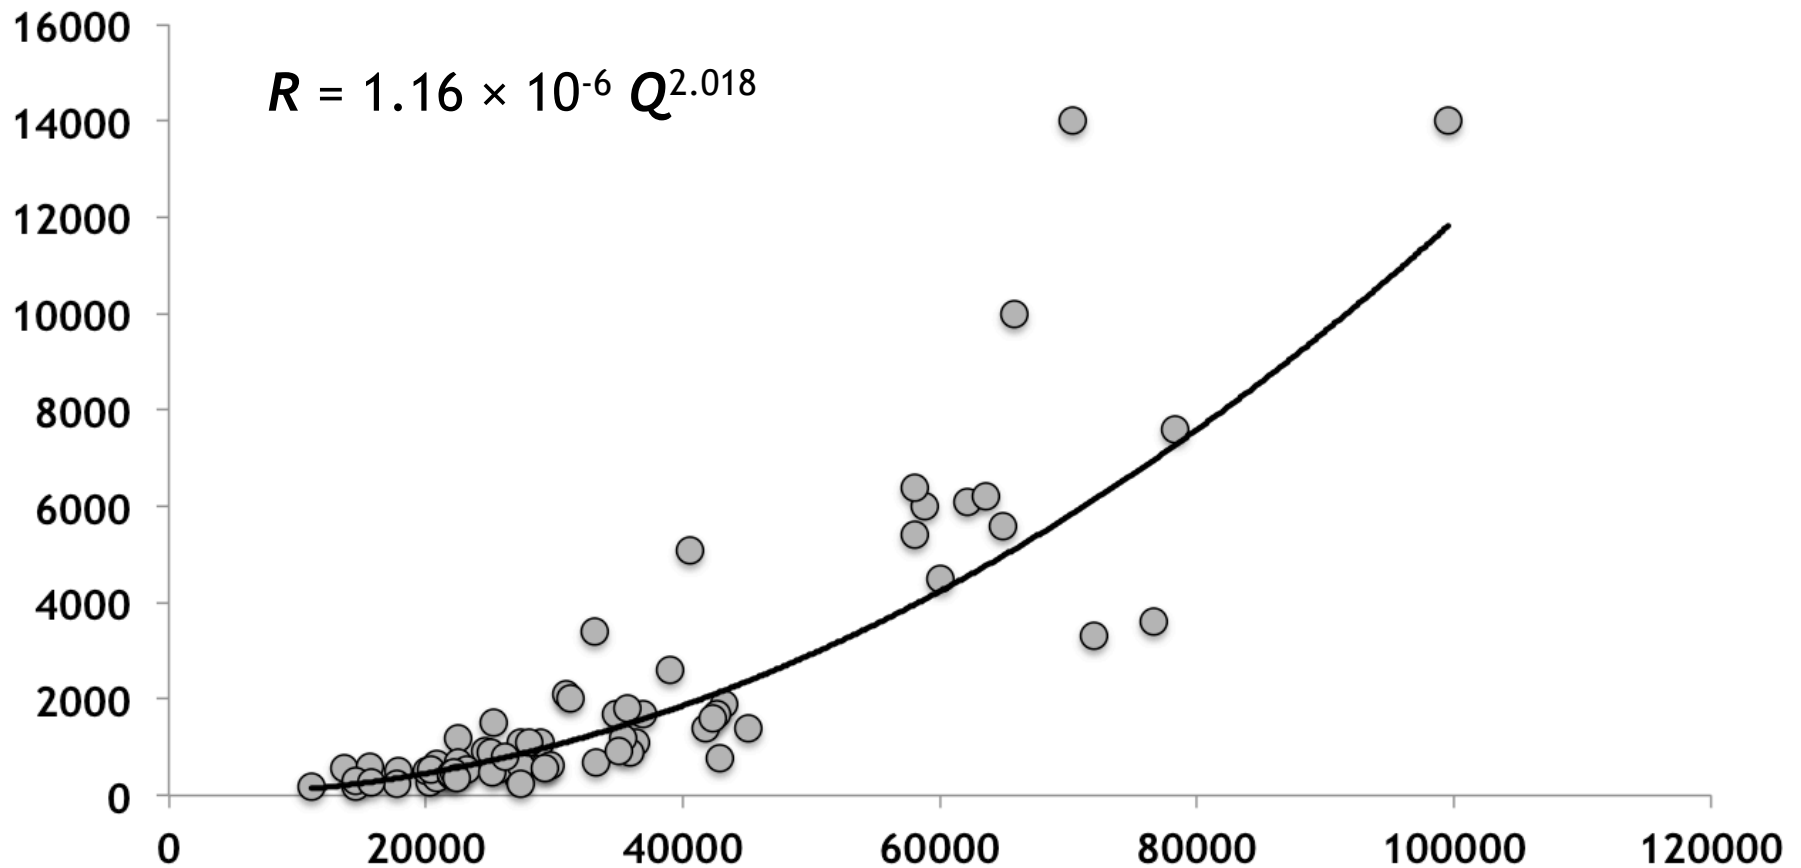

$$\text{SSC} = aQ^b$$

‘Coloured box’ regression model and, as such, an optimization problem (best fit).

3. *A tool*

Sediment rating curves are extensively used in daily (monthly, ...) sediment load calculations, forecasts and river management planning.

Sediment Rating Curve: Lena at Kyusyur (1961-1977)

Model errors

Model errors

Suspended load estimates

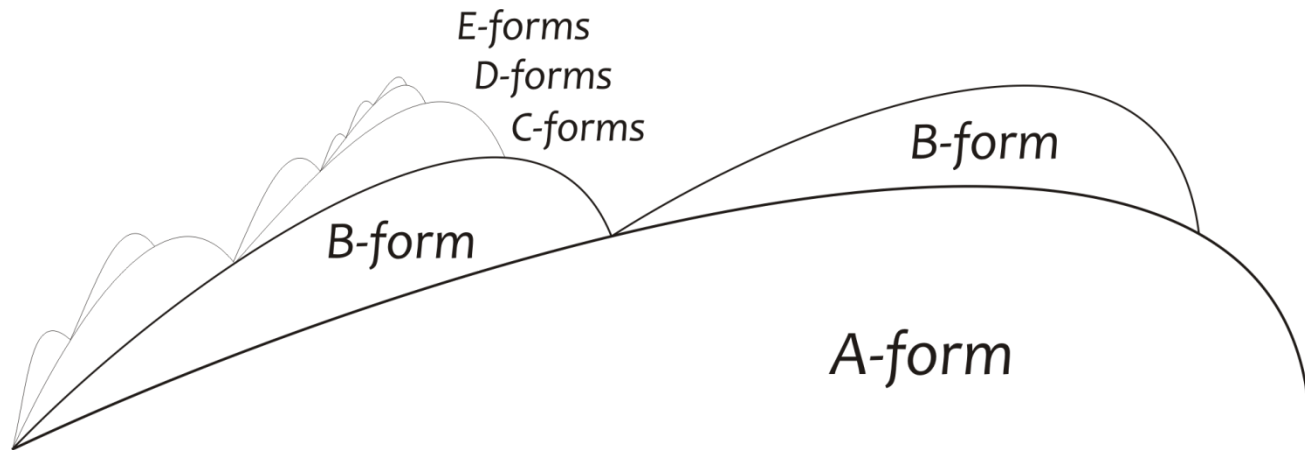

Consistent suspended sediment flux:
 20.7 ± 0.3 Mt

Strongly seasonal flux (June):
ca. 60% (12.4 Mt)

Supply to the delta margin:
10 to 17% [Rachold et al., 1996]

Bed load calculations [Alekssevskiy, 2004]

$$g_{\Gamma} = k \cdot \sigma^* \cdot h_{\Gamma} \cdot C_{\Gamma},$$

Here k stands for dimensionless bedform coefficient, σ^* - sediment density, h_{Γ} - bedform height, C_{Γ} - bedform movement rate. Computations are carried out for each hydrological season separately (from [Alexeevsky, 1998]).

Bed load estimations [Tananaev, Anisimova, 2013]

Sediment delivery to the Lena River delta region

Total sediment delivery: **36 Mt**

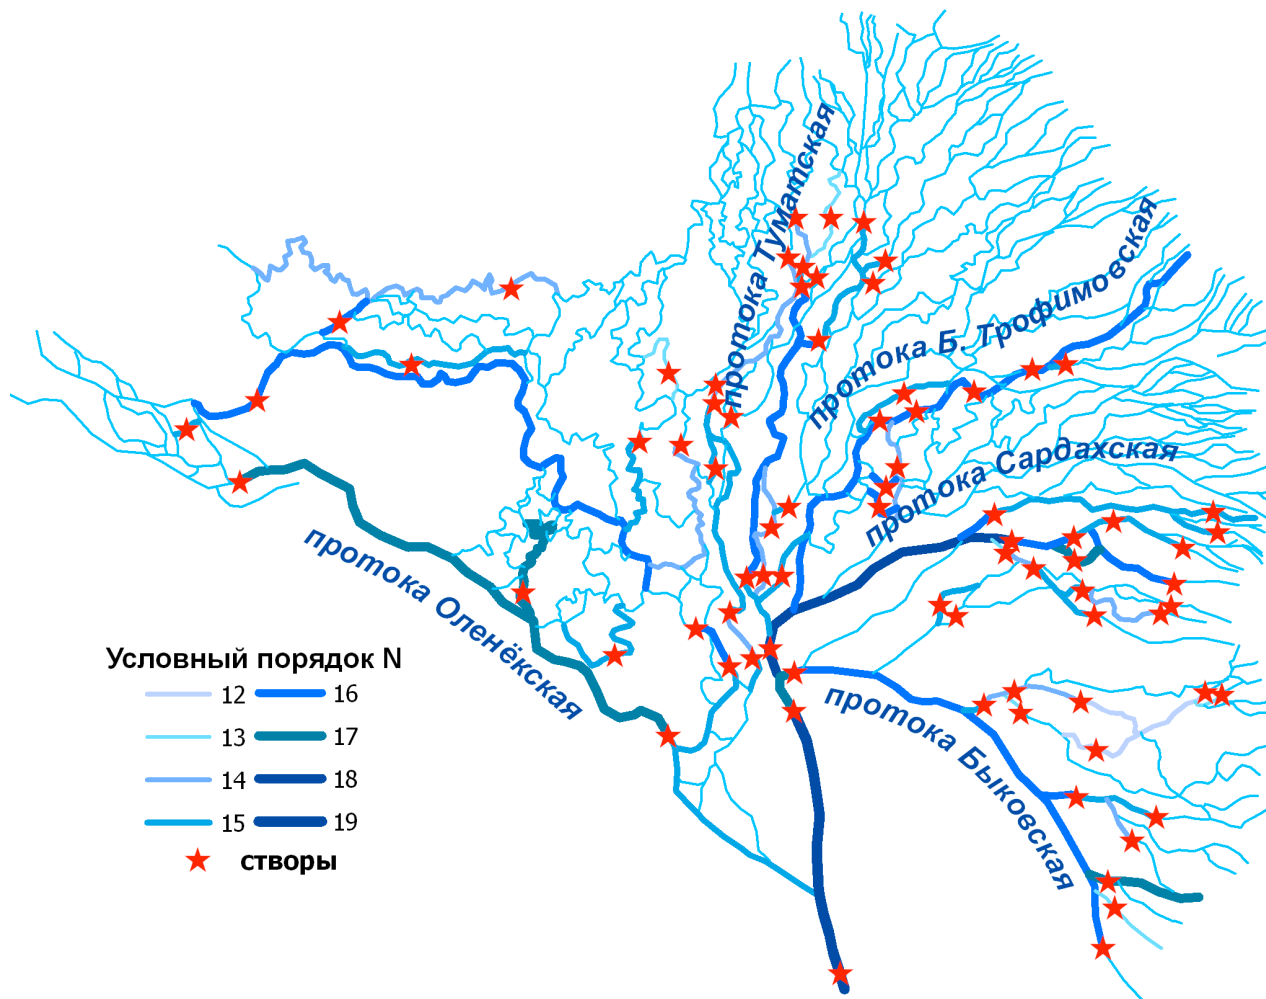

➤ 21 Mt as suspended material

➤ 15 Mt as bed load

➤ 2-4 Mt reach the delta margin

➤ Surge events [Rivera et al., 2006] ~ 17 events during the last 2000 yr;

Water redistribution in the delta region: conditional stream order [Alekseevsky et al., 2013]

$$N = 1 + \log_2 P(1)$$

[Scheidegger, 1966]

$$N \sim Q$$

$$P_i / P(1) = Q_i / Q$$

$$N_i = 1 + \log_2 P_i$$

Environmental Implications: (1) Discharge increase

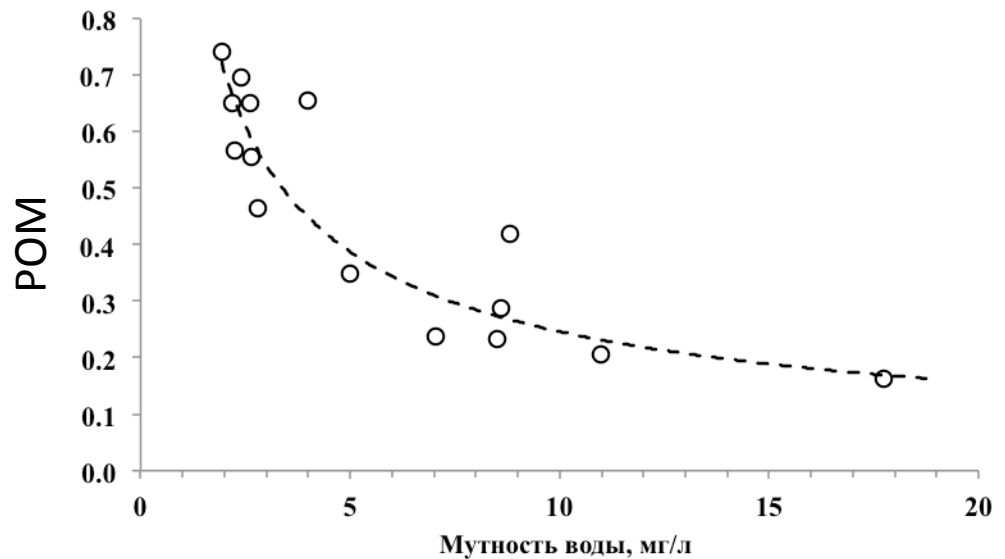

+22% Ensemble-averaged
+130 mm Spring runoff
+ 13 Mt Suspended load
+ 2 Mt Bed load

Environmental Implications: (2) Organic matter supply

Oubangui R. [Bouillion et al., 2012]

Graviyka R. [Tananaev, in press]

Organic carbon content in suspended matter varies regionally.
Assume 20% of suspended load is actually POM: 4 Mt, POC: 1.8 Mt
DOC flux [Amon et al., 2012]: 6.47 Mt

Environmental Implications: (3) Hg fluxes

10/10/2013 Russia signs
Minamata Convention
on Mercury

Conclusions

- Sediment fluxes are hardly quantifiable given the quality and quantity of the data used;

Further research directions:

- Heat fluxes associated with sediment accumulation within the floodplain and alluvial bars;
- Quality, age and fate of the particulate organic matter entering the delta region [Guo et al., 2007; Hahn-Schofl et al., 2011; Gustaffson et al., 2011]
- Chemical composition of the particulate matter; heavy metals, rare earth metals [Rachold et al., 1996]
