

The Climate-system Historical Forecast Project (CHFP)

CITES2019

Ramiro Saurral (CIMA, Buenos Aires, Argentina)

Moscow, Russia. 28 May 2019

Background and main objectives of CHFP

First steps...

The CHFP was born in 2007 as part of the Working Group on Seasonal to Interannual Prediction (currently Working Group on Subseasonal to Interdecadal Prediction; WGSIP), having the nature of a multi-model and multi-institutional experimental framework for **sub-seasonal to decadal complete physical climate system** prediction.

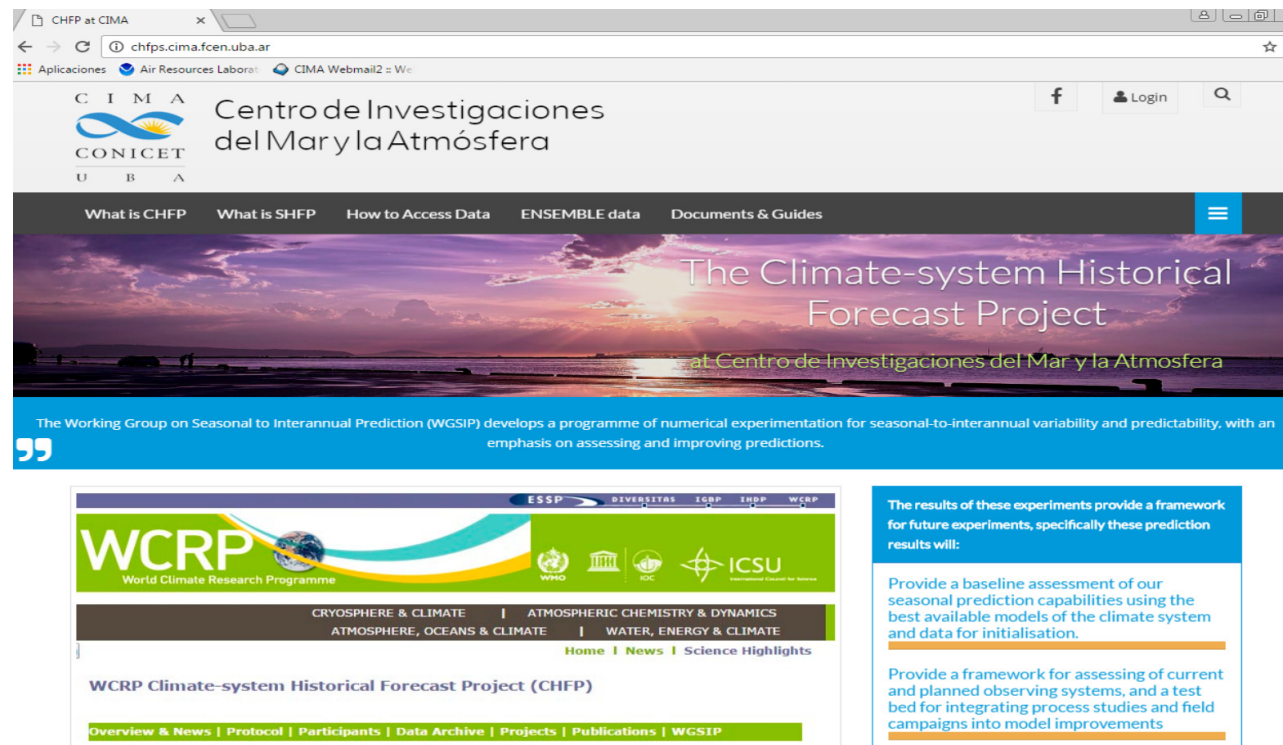

By the complete physical climate system, we mean contributions from the atmosphere, oceans, land surface cryosphere and atmospheric composition in producing regional and sub-seasonal to decadal climate anomalies. This experimental framework is based on advances in climate research during the past years, which have lead to the understanding that modeling and predicting a given climate anomaly over any region is incomplete without a proper treatment of the effects of SST, sea ice, snow cover, soil wetness, vegetation, stratospheric processes, and atmospheric composition (carbon dioxide, ozone, etc.). **CHFP is particularly focused on the sub-seasonal to seasonal scale.**

Objectives

- Provide a baseline assessment of our seasonal prediction capabilities using the best available models of the climate system and data for initialisation
- Provide a framework for assessing of current and planned observing systems, and a test bed for integrating process studies and field campaigns into model improvements
- Provide an experimental framework for focused research on how various components of the climate system interact and affect one another
- Provide a test bed for evaluating IPCC class models in seasonal prediction mode

An introduction to CHFP

- The CHFP database hosts forecast systems outputs from retrospective predictions of the seasonal global climate from year to year, initialized at least twice a year across recent decades, and is freely available for research use.

<http://chfps.cima.fcen.uba.ar/>

Is monthly initialization worth the computational cost?

FIG. 2. (left) Seasonal-mean Niño-3.4 index (area-averaged SST anomaly in 5°S–5°N, 170°–120°W), as observed (OISST analysis; black) and predicted by CHFP models (red) initialized from February, May, August, and November 1982–2009 at (a) 0-, (b) 3-, and (c) 6-month lead times. Circles indicate mean values and error bars indicate standard deviations of predictions from 95 ensemble members. (right) Comparison of CHFP anomaly correlation skill values with those based on persisting the observed Niño-3.4 value prior to the start of the forecast.

From Tompkins et al. (2017), BAMS

The CHFP database currently contains data from 16 coupled forecast systems and hosts more than 10 TB of information in NetCDF format.

It is continuously growing and will continue to do so over the coming years to serve as a record of progress in global seasonal forecasting capability.

Forecast system	Research Center/Country
ARPEGE	MétéoFrance (France)
CCCma-CanCM3	CCCma (Canada)
CCCma-CanCM4	CCCma (Canada)
CFS	NCEP (USA)
CMAM	Canada
CMAMlo	Canada
ECMWF-S4	ECMWF (UK)
GloSea5	MetOffice (UK)

Forecast system	Research Center/Country
JMA/MRI-CGCM1	JMA (Japan)
JMA/MRI-CGCM2	JMA(Japan)
L38GloSea4	MetOffice (UK)
L85GloSea4	MetOffice (UK)
MIROC5	CCSR (Japan)
MPI-ESM-LR	MPI (Germany)
MPI-ESM-MR	MPI (Germany)
POAMA	BoM (Australia)

Near future: NMME (Phase 1 and 2), RHMC SL-AV, SINTEX-2

- According to CHFP protocols, forecast systems within CHFP **MUST** include seasonal (4-month lead-time) forecasts initialized **AT LEAST** twice a year, in May and November. If available, additional start times are also welcome (several models have start times every month, or 4 times a year, which is of course useful).
- Data from each forecast system is hosted in its native resolution (i.e. there is not any regridding onto a same grid).
- CHFP hosts both monthly mean and daily data.
- Forecasts start near 1979 and end around 2010.
- Some of the variables included in CHFP are 2m mean, minimum and maximum temperatures, total precipitation, zonal and meridional winds, heat fluxes and soil moisture, among others for the atmosphere, while several others are available related to the ocean (SST, sea ice, ...)

Abstract This work presents an analysis of the ability and skill of climate anomalies. The study was made considering of seasonal forecasts for surface temperature and regional circulation, from models included in the CHFP Project. Predictability was evaluated of the signal-to-total variance ratio was assessed computing anomaly. Both indicators present over the at the tropics than at the extratropics temperature and precipitation. Model prediction skill for temperature as than in JJA while for precipitation skill for both variables and seasonal western South America while model values for extratropical precipitation America and the extratropical A levels in ENSO years of both variables although with the same spatial

Predictability of the tropospheric circulation in the Northern Hemisphere from CHFP models

Marisol Osman¹ · C. S. Vera¹ · F. J. Doblas-

Received: 16 October 2014 / Accepted: 8 June 2015
© Springer-Verlag Berlin Heidelberg 2015

Abstract An assessment of the predictability of the tropospheric circulation in the Northern Hemisphere was done. The analysis is based on forecasts of geopotential heights at 200, 500 and 1000 hPa for austral summer and winter from 11 models included in the Climate Historical Forecast Project. Both predictability (signal-to-variance ratio) and skill (anomaly correlation) in the tropics is higher in the extratropics and is also higher in summer than in winter. Both predictability and skill are higher at low altitudes. Modest values of predictability are found at polar latitudes in the Bellinghousen Seas. The analysis of the changes in predictability skill in ENSO events reveals that both are higher in the El Niño-Southern Oscillation (ENSO) than in La Niña years. Changes in signal-to-variance ratio observed are mainly due to signal changes than changes in noise. Composites of geopotential anomalies for El Niño and La Niña years are in good agreement with observations.

Using an international, multi-model suite of historical reanalyses and the WCRP Climate-system Historical Forecast Project (CHFP) data, we compare the seasonal prediction skill in boreal winter for the stratosphere and its dynamics ('high-top') at 10 hPa and evaluate hindcasts that are initialized in November for the stratosphere and how they relate to boreal winter forecast skill. We are unable to detect more skill in the low-top ensemble-mean in forecasting the winter model performance varies widely. Increasing the ensemble size for a given model. We then examine two major processes involving stratosphere–troposphere interactions (the El Niño/Southern Oscillation (ENSO) and the Quasi-Biennial Oscillation (QBO)) and how they relate to predictive skill on intraseasonal to seasonal time-scales, particularly over the North Atlantic and Eurasia regions. High-top models tend to have a more realistic stratospheric response to El Niño and the QBO compared to low-top models. Enhanced conditional wintertime skill over high latitudes and the North Atlantic region during winters with El Niño conditions suggests a possible role for a stratospheric pathway. Compiling retrospective forecasts made with state-of-the-

UNCERTAINTY IN SEASONAL FORECASTING. Any prediction of the future evolution of the Earth system requires an associated assessment of its uncertainty. This is true whether the forecast is for the days ahead or is a longer-term prediction for the following months and seasons.

For seasonal forecasts, the uncertainty associated with inexact initial conditions, which can grow rapidly in time, is usually addressed by running multiple forecasts with perturbations applied to the initial state of the ocean and atmosphere (Arribas et al. 2011; Stockdale et al. 2011). The idea is that the perturbed initial conditions are of a suitable magnitude to represent the uncertainty in the observational measurements and the analysis tools that are

used to process them. As the forecast evolves, the differences between the forecasts, known as the ensemble "spread," should therefore reflect the typical forecast error, or "uncertainty"; in other words, the eventual real-world evolution should be contained within the cluster of this forecast ensemble. In tandem, uncertainty in forecasts is also contributed to by our inexact representations of the Earth system physics. This contribution to uncertainty is sampled by employing different Earth system models (Yun et al. 2005; Weisheimer et al. 2009; Smith et al. 2013), the so-called multimodel approach, which is often supplemented by the use of perturbations to physical processes, known as stochastic physics schemes, to further account for structural errors in a particular

How to access the data

Downloading and using CHFP is very easy! The steps are:

1) Register at the CHFP website (<http://chfns.cima.fcen.uba.ar>)

The screenshot shows the CIMA-CHFP/SHFP website interface. The header includes the CIMA logo, the text "CIMA-CHFP/SHFP", and navigation links "Home", "Data", and "Catalog". The user is logged in as "User: Saurral, Ramiro". The main content area is titled "CHFP/SHFP Atmosphere - Surface - Monthly". It features a "Select Initial Start Month" table with columns for years (1979-2019) and months (Feb, May, Aug, Nov). Below this is a "Select Model" section with checkboxes for various climate models: ARPEGE*, CCCma-CanCM3, CCCma-CanCM4, CFS*, CMAM*, CMAMlo, ECMWF-S4*, Glo Sea5*, JMAMRI-CGCM1, JMAMRI-CGCM2, L38Glo Sea4, L85Glo Sea4*, MIROC5, MPI-ESM-LR*, and poama.

CHFP 2 Automata Server

How to access the data

Files can be downloaded individually or (more efficiently) using scripts.
An easy way to go in Linux is to download the list of files and use wget...

- Save the list of files (received by email) in a .txt file (e.g. file_list.txt)

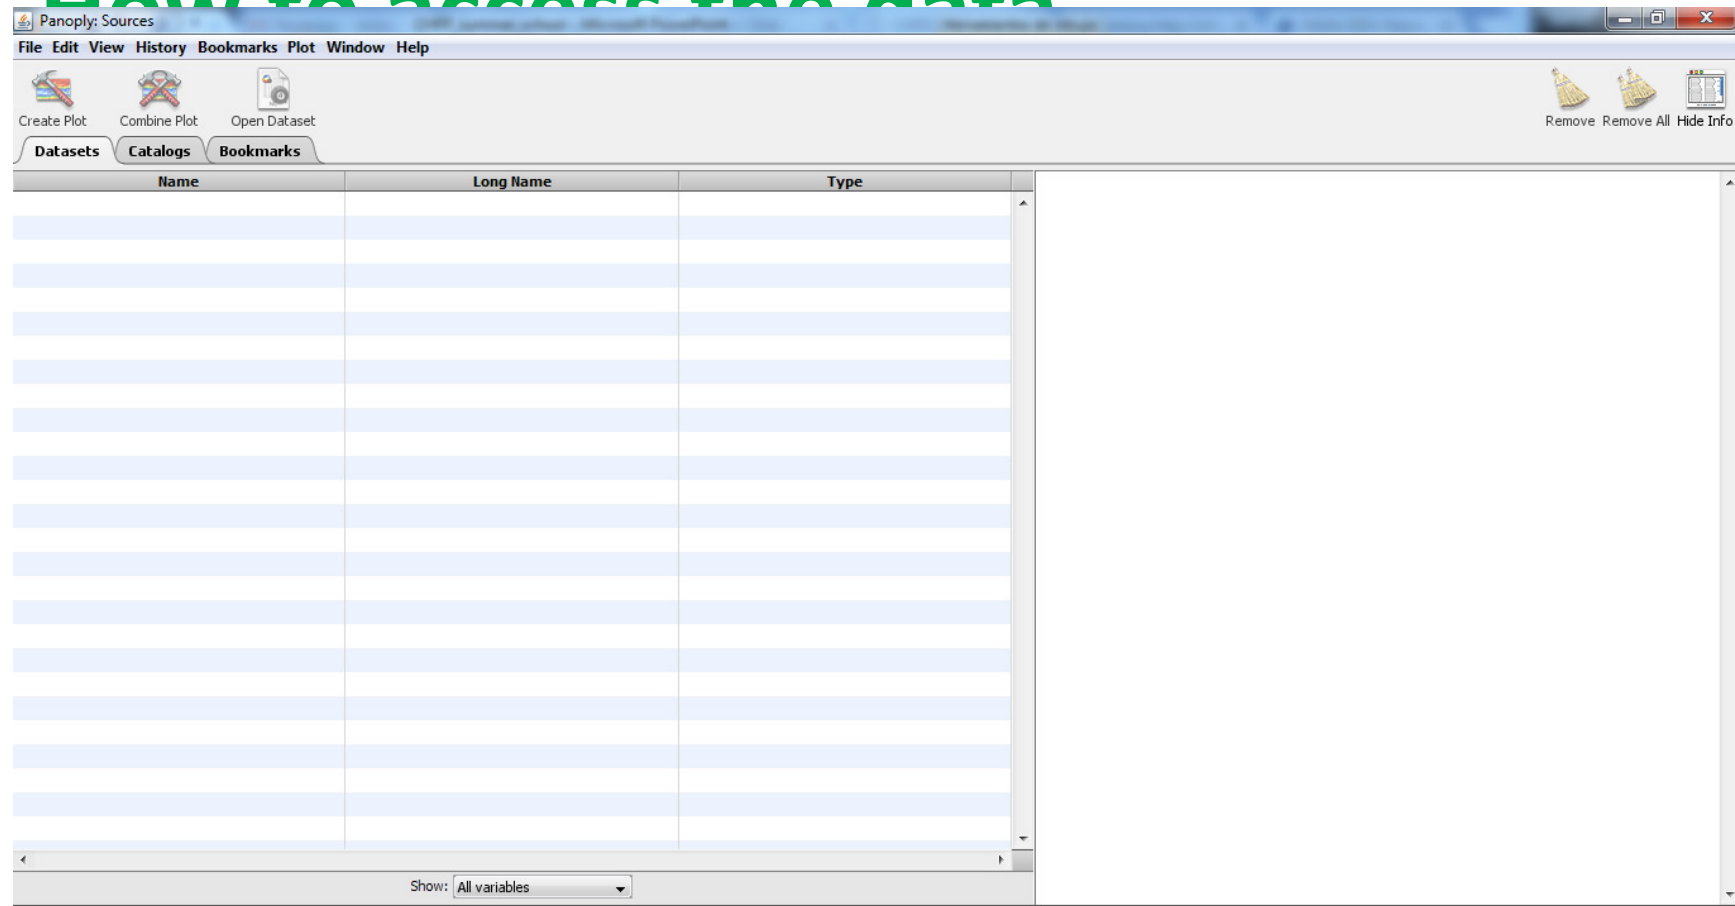

```
http://chfps.cima.fcen.uba.ar/request/20140128131722/tasmin_monthly_ECMWF-S4_CHFP_19810201.nc  
http://chfps.cima.fcen.uba.ar/request/20140128131722/tasmin_monthly_ECMWF-S4_CHFP_19820201.nc  
http://chfps.cima.fcen.uba.ar/request/20140128131722/tasmin_monthly_ECMWF-S4_CHFP_19830201.nc
```

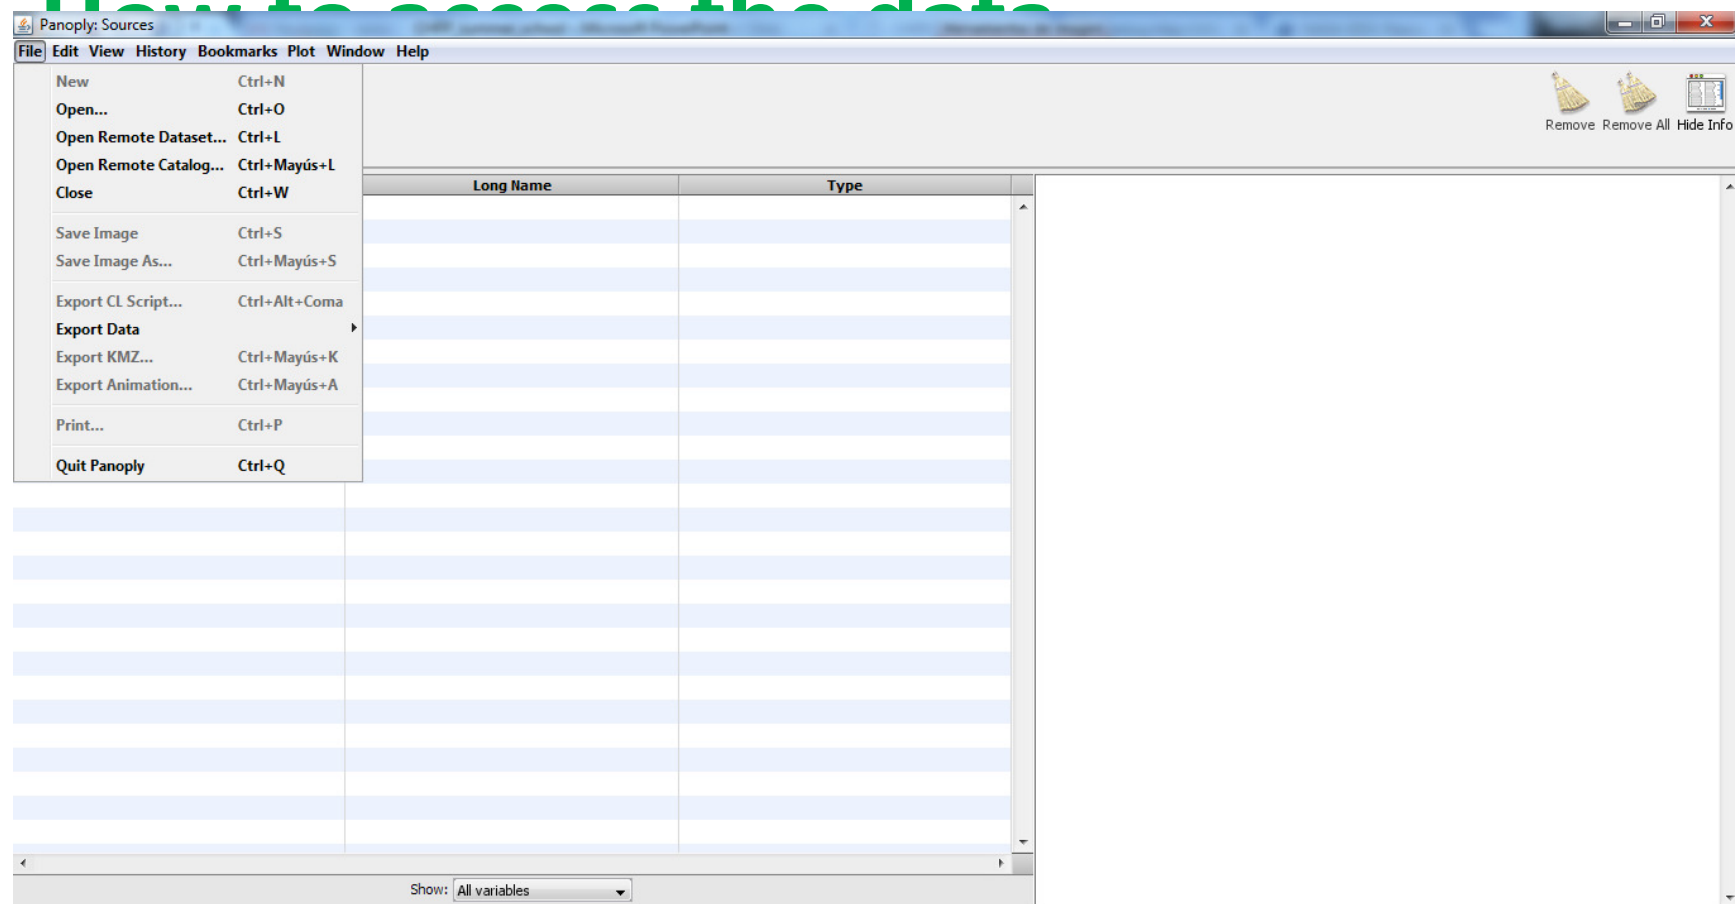

- Use wget:

```
$ wget -b -c -nd t=0 -i file_list.txt -o log_01
```

In the example above, file “log_01” will contain all the information regarding the download speed and status.

How to access the data

How to access the data

Another good option is to use OpenDAP, which allows to use NCO tools to subset, split and merge files before download.

NCO tools:

nco.sourceforge.net

Quick introduction to NCO tools

Cut files (along the dimension of a variable): ncks

Example: Want to keep only latitudes from 0 to 20N

```
$ ncks -d latitude,0.,20. [input file] [output file]
```

Merge files: nccat

```
$ nccat precip* precip_merged.nc
```
